Risk factors include being overweight, previously having gestational diabetes, a family history of type 2 diabetes, and having polycystic ovarian syndrome. Diagnosis is by blood tests. For those at normal

risk, screening is recommended between 24 and 28 weeks' gestation. For those at high risk, testing may occur at the first prenatal visit. **History** Metformin is a biguanide anti-hyperglycemic agent. It works by decreasing glucose production in the liver, increasing the insulin sensitivity of body tissues, and increasing GDF15 secretion, which reduces appetite and caloric intake. Flupentixol acts as a dopamine 1 and 2 receptor antagonist and melitracen acts in similar way to other tricyclic antidepressants blocking the reuptake of serotonin and norepinephrine in presynaptic terminals.

Diabetes management There are several preparations of the medication such as tablets, extend release tablets, and liquid suspensions Diabetes mellitus is a metabolic disease that is characterized by chronic elevated blood glucose levels (hyperglycemia). Insulin production in order to be effective. Therefore, the main goal of diabetes management is to keep blood glucose levels within normal limits (or a diabetic target range) as often as possible. Other goals of diabetes management are prevention or treatment of complications that can result from the disease itself and from its treatment. Long-term glucose levels (over 3 months) can also be measured by analysis of a blood sample. People with diabetes can measure blood glucose by various methods, such as with a glucose meter or a continuous glucose monitor, which monitors over several days. If diabetes is not well controlled, health challenges may develop. In addition to lifestyle modification, some individuals with type 2 diabetes may require medication to adequately control their blood glucose levels.
