Attachment in adults Dismissive-avoidant attachment is one of the main attachment styles, and is often In psychology, the theory of attachment in adults examines the way in which emotional connections are approached during adulthood across a spectrum of relationship types, which is posited to originate from the bonding experience received from caregivers as an infant. anxious attachment individuals worry about the state of the relationship 68d0358c6a

Internal working model of attachment This model is a result of interactions with primary caregivers which become internalized, and is therefore an automatic process. This is mostly the case for dismissive-avoidant attachment where conflicting ideas of the caregiver as both Internal working model of attachment is a psychological concept that describes the development of mental representations of the self's worthiness and expectations of others' responses. John Bowlby implemented this model in his attachment theory in order to explain how infants act in accordance with these mental representations. It is an important aspect of general attachment theory. subconscious to prevent a threat to the self 68d0358c6a

Not precisely known, the causes of AvPD are believed to involve several environmental and genetic factors. The disorder is chronic, and research is limited with regard to its treatment. Treatment and time may allow for the condition to be ameliorated. Ostensibly, it affects a similar number of women as it does men, with some indication of a higher prevalence among women. 68d0358c6a The most

influential figure for the idea of the internal working model of attachment is Bowlby, who laid the groundwork for the concept in the 1960s. He was inspired by both psychoanalysis, especially object relations theory, and more recent research into ethology, evolution and information-processing.

Avoidant personality disorder People with AvPD may therefore avoid social interaction, while at the same time strongly desiring more involvement with other people. Avoidant personality disorder (AvPD), or anxious personality disorder, is a personality disorder characterized by marked social inhibition and avoidance Avoidant personality disorder (AvPD), or anxious personality disorder, is a personality disorder characterized by marked social inhibition and avoidance, accompanied by feelings of inadequacy and a strong sensitivity to rejection or negative evaluation 68d0358c6a

Attachment parenting There is no conclusive body of research that shows Sears' approach to be superior to "mainstream parenting". The term attachment parenting was coined by the American pediatrician William Sears. Attachment parenting (AP) is a parenting philosophy that proposes methods aiming to promote the attachment of mother and infant not only by maximal parental Attachment parenting (AP) is a parenting philosophy that proposes methods aiming to promote the attachment of mother and infant not only by maximal parental empathy and responsiveness but also by continuous bodily closeness and touch 68d0358c6a

Mary Ainsworth and John Bowlby founded the modern-day attachment theory on studies of children to their caregivers. Children and caregivers remained the primary focus of attachment theory for many years but, in the 1980's, Sue Johnson began using attachment theory in adult therapy settings. Cindy Hazan and Phillip Shaver continued to conduct research through analyzing adult relationships. Hazan and Shaver noticed that interactions between adults were similar to interactions between children and

caregivers. Adults feel comforted when their attachment figures are present, but feel more anxious, and/or lonely, when... 68d0358c6a Many assessments allow children and adults' attachment strategies to be classified into three primary attachment pattern groups: B-pattern (autonomous, balanced, blended, secure), A-pattern (avoidant, dismissive, cognitive, insecure), and C-pattern (ambivalent, preoccupied, resistant, affective, insecure). In most models, each pattern group is further broken down into several sub-patterns. Some assessments can find additional information about an individual, such as unresolved trauma, depression, history of family triangulation, and lifespan changes in the attachment pattern. Some assessments specifically or additionally look for caregiving behaviors, as caregiving and attachment are considered two separate systems for organizing thoughts, feelings, and behavior. Some methods assess disorders of attachment or romantic attachment. 68d0358c6a

Attachment and health In 1982, American psychiatrist Lawrence Kolb noticed that patients with chronic pain displayed behaviours with their healthcare providers akin to what children might display with an attachment figure, thus marking one of the first applications of the attachment theory to physical health. Since that time, it has been used to understand variations in stress response, health outcomes and health behaviour. Ultimately, the application of the attachment theory to health care may enable health care practitioners to provide more personalized medicine by creating a deeper understanding of patient distress and allowing clinicians to better meet their needs and expectations. creating a cycle of distress-withdrawal-distress. Development of the adult attachment theory and adult attachment measures in the 1990s provided researchers with the means to apply the attachment theory to health in a more systematic way. Avoidant-dismissive people with avoidant dismissive attachment emphasize their independence and minimizing Attachment and health is a psychological model which considers how the attachment theory pertains to people's preferences and expectations for the proximity of others when faced with stress, threat, danger or pain 68d0358c6a

Attachment theory has led to a new understanding of child development. Children develop different patterns of attachment based on experiences and interactions with their caregivers at a young age. Four different attachment classifications have been identified in children: secure attachment, anxious-ambivalent attachment, anxious-avoidant attachment, and disorganized attachment. Attachment theory has become the dominant theory used today in the study of infant and toddler behavior and in the fields... 68d0358c6a

Attachment theory In the 1980s, attachment theory was extended Attachment theory is a psychological and evolutionary framework concerning the relationships between humans, particularly the importance of early bonds between infants and their primary caregivers. Developed by psychiatrist and psychoanalyst John Bowlby (1907–90), the theory posits that infants need to form a close relationship with at least one primary caregiver to ensure their survival, and to develop healthy social and emotional functioning. distress, and identified attachment patterns in infants: secure, avoidant, anxious, and disorganized attachment 68d0358c6a

RAD arises from a failure to form normal attachments to primary caregivers in early childhood. Such a failure could result from severe early experiences of neglect, abuse, abrupt separation from caregivers between the ages of six months and three years, frequent changes of caregivers, or a lack of caregiver responsiveness to a child's communicative efforts. It is differentiated from pervasive developmental disorder or developmental delay and from possibly comorbid conditions such as intellectual disability, all of which can affect attachment behavior. The criteria for a diagnosis of reactive attachment disorder are very different from the... 68d0358c6a Secure attachment is an under-explored topic beyond infancy, however some research indicates that attachment security continues to influence relationships, emotional regulation, and psychological well-being throughout adulthood. 68d0358c6a

Secure attachment Children with secure attachment feel protected by their caregivers, and they know that they can depend on them to return. main types of attachment: secure attachment, ambivalent attachment, avoidant attachment and disorganized attachment. A securely attached child can use their parent as a safe base to explore their surroundings and is easily comforted after being separated or when feeling stressed. Ambivalent attachment is defined by Secure attachment is classified by children who show some distress when their caregiver leaves but are able to compose themselves quickly when the caregiver returns 68d0358c6a

Pivotal aspects of attachment theory include the observation that infants seek proximity to attachment figures, especially during stressful situations. Secure attachments are formed when caregivers are sensitive and responsive in social interactions, and consistently present, particularly between the ages of six months and two years. As children grow, they use these attachment figures as a secure base from which to explore the world and return to for comfort. The interactions with caregivers form patterns of attachment, which in turn create internal working models that influence future relationships. Separation anxiety or grief following the loss of an attachment figure is considered to be a normal and adaptive response for an attached infant... 68d0358c6a == History == 68d0358c6a Such internal working models guide future behavior as they generate expectations of how attachment figures will respond to one's behavior. For example, a parent rejecting the child's need for care conveys that close relationships should be avoided in general, resulting in maladaptive attachment styles. 68d0358c6a == Background == 68d0358c6a Attachment theory was initially studied in the 20th century to associate infant behaviors with the attachment they had to their caregivers. The working models of children found in John Bowlby's attachment theory demonstrate a pattern of interaction which is likely to influence adult relationships. 68d0358c6a Attachment models are typically generated from the... 68d0358c6a

Attachment measures As research accumulated and atypical patterns of attachment became Attachment measures, or attachment assessments, are procedures used to assess the attachment system in children and adults. These procedures can assess patterns of attachment and individual self-protective strategies. Some assessments work across the several models of attachment and some are model-specific. into the attachment styles known as secure, anxious-avoidant and anxious-ambivalent 68d0358c6a

Attachment in children Attachment also describes the function of availability, which is the degree to which the authoritative figure is responsive to the child's needs and shares communication with them. Attachment behaviour anticipates a response by the attachment figure which will remove threat or discomfort". Attachment is found in all mammals to some degree, especially primates. in children: secure attachment, anxious-ambivalent attachment, anxious-avoidant attachment, and disorganized attachment. Childhood attachment can define characteristics that will shape the child's sense of self, their forms of emotion-regulation, and how they carry out relationships with others. Attachment theory has become the Attachment in children is "a biological instinct in which proximity to an attachment figure is sought when the child senses or perceives threat or discomfort 68d0358c6a

Reactive attachment disorder In the DSM-5, the "disinhibited form" is considered a separate diagnosis named "disinhibited social engagement disorder". It can take the form of a persistent failure to initiate or respond to most social interactions in a developmentally appropriate way—known as the "inhibited form". RAD primarily affects children, although these issues do occasionally persist into adulthood. Reactive attachment disorder (RAD) is an attachment disorder characterized by markedly disturbed and developmentally inappropriate ways of relating socially Reactive attachment disorder (RAD) is an attachment disorder characterized by markedly disturbed and developmentally inappropriate ways of relating socially in most contexts 68d0358c6a

Attachment behavior allows an infant to draw people near them when they are in need of help or are in distress. Humans' instinct for attachment is a basic adaptation for survival that most mammals share, and when infants and adults feel stresses or are under alert, their attachment system is alerted.
