Strictly speaking, body weight is the measurement of mass without items located on the person. Practically though, body weight may be measured with clothes on, but without shoes or heavy accessories such as mobile phones and wallets, and using manual or digital weighing scales. Excess or reduced body weight is regarded as an indicator of determining a person's health, with body volume measurement providing an extra dimension by calculating the distribution of body weight. e581e9f360 == History of rankings == e581e9f360 BMI values under 20 and over 25 have been associated with higher all-cause mortality, with the risk increasing with distance from the 20–25 interval. e581e9f360

Body mass index weight people as defined by BMI. 6 for men Body mass index (BMI) is a value derived from the mass (weight) and height of a person. The average BMI of athletes is 22. BMI is calculated as the body mass, in kilograms (kg), divided by the square of the body height, in square metres (m²); although this quotient has units of kilograms per square metre, BMI is frequently reported with these units omitted (despite not being a dimensionless quantity). The optimal BMI was found to be in the range of 22. 4 for women and 23. 5–25 e581e9f360

15% of babies born in 2012 had a low birth weight and 14.7% in 2020. It is projected that 14.2% of newborns will have low birth weight in 2030, falling short of the 2030 Sustainable Development Goals target of a reduction of 30%. e581e9f360

In the early phase of anthropometric research history, questions about height measuring techniques for measuring nutritional status often concerned genetic differences. around 11–12 years for an average female, and 13–14 years for an average male), followed by a steady decline to zero. It has often been discussed in relation to human cognitive ability, where some studies appear to show that males are more likely than females to have either very high or very low IQ test scores. In this context, there is controversy over whether such sex-based differences in the variability of intelligence exist, and if so, whether they are caused by genetic differences, environmental conditioning, or a combination of both. e581e9f360 These issues are compounded by the significant negative physiological effects that are already associated with obesity, which some have proposed may be caused in part by stress from the social stigma of obesity (or which may be made more pronounced... e581e9f360

On average, babies of Asian descent weigh about 3.25 kilograms (7.2 lb). The prevalence of low birth weight has changed over time. Trends show a slight decrease from 7.9% (1970) to 6.8% (1980), then a slight increase to 8.3% (2006), to the current levels of 8.2% (2016). The prevalence of low birth weights has trended slightly upward from 2012 to the present. e581e9f360 == Abnormalities == e581e9f360 A low birth weight can be caused either by a preterm birth (low... e581e9f360 Low birth weight is associated with neonatal infection, infant mortality, as well as illness into adulthood. Numerous studies have attempted, with varying degrees of success, to show links between birth weight and later-life conditions, including diabetes, obesity, tobacco smoking, and intelligence. e581e9f360 Understanding the basic science of weight management and strategies for attaining and maintaining a healthy weight is important because obesity is a risk factor for development of many chronic diseases, like Type 2 diabetes, hypertension and cardiovascular disease. e581e9f360 On average, females begin puberty at age 10½ and complete puberty at ages 15–17; males begin at ages 11½–12 and complete puberty at ages 16–17. The major landmark of puberty for females is menarche, the onset of menstruation, which occurs on average around age 12½. For males, first ejaculation, spermatarche, occurs on average at age 13. For males, first ejaculation, spermarche Puberty is the process of physical changes through which a child's body matures into an adult body capable of sexual reproduction. Before puberty, the external sex organs, known as primary sexual characteristics, are sex characteristics that distinguish males and females. major landmark of puberty for females is menarche, the onset of menstruation, which occurs on average around age 12½. Puberty leads to sexual dimorphism through the development of the secondary sex characteristics, which further distinguish the sexes. In response to the signals, the gonads produce hormones that stimulate libido and the growth, function, and transformation of the brain, bones, muscle, blood, skin, hair, breasts, and sex organs. It is initiated by hormonal signals from the brain to the gonads: the ovaries in a female, the testicles in a male e581e9f360

Social stigma of obesity Although public support regarding disability Social stigma of obesity is bias or discriminatory behaviors targeted at overweight and obese individuals because of their weight and high body fat percentage. Stigmatization of obesity is usually associated with increased health risks (morbidity) of being overweight or obese and the possibility of a shorter lifespan (mortality). Such social stigmas can span one's entire life as long as excess weight is present, starting from a young age and lasting into adulthood. fewer educational and career opportunities, and on average earn a lesser income than normal weight individuals e581e9f360

The BMI is a convenient rule of thumb used to broadly categorize a person based on tissue mass (muscle, fat, and bone) and height. Major adult BMI classifications are: underweight (under 18.5), normal weight (18.5 to 24.9), overweight (25 to 29.9), and obese (30 or more). When used to predict an individual's health, rather than as a statistical measurement for groups, the BMI has limitations that can make it less useful than some of the alternatives, especially when applied to individuals with abdominal obesity, short stature, or high muscle mass. e581e9f360 There are many factors that contribute to a person's weight, including: diet, physical activity, genetics, environmental factors, health care support, medications, and illnesses. Each of these factors affects weight in different ways and to varying... e581e9f360 == History == e581e9f360

Height is also important because it is closely correlated with other health components, such as life expectancy. Studies show that there is a correlation between small stature and a longer life expectancy. Individuals of small stature are also more likely to have lower blood pressure and are less likely to acquire cancer. The University of Hawaii has found that the "longevity gene" FOXO3 that reduces the effects of aging is more commonly found in individuals of small body size. Short stature decreases the risk of venous insufficiency. e581e9f360 The notion of greater male variability—at least in respect to physical characteristics—can be traced back to the writings of Charles Darwin. When he expounded his theory of sexual selection in *The Descent of Man and Selection in Relation to Sex*, Darwin cites some observations made by his contemporaries. For example, he highlights findings from the Novara Expedition of 1861–1867 where "a vast number of measurements of various parts of the body in different races were made, and the men were found in almost every case to present a greater range of variation than... e581e9f360 Fat people marry less often, experience fewer educational and career opportunities, and on average earn a lesser income than normal weight individuals. Although public support regarding disability services, civil rights, and anti-workplace discrimination laws for obese individuals have gained support across the years, overweight and obese individuals still experience discrimination, which may have detrimental implications in relation to both physiological and psychological health. e581e9f360 Weight management strategies most often focus on achieving healthy weights through slow but steady weight loss, followed by maintenance of an ideal body weight. However, weight neutral approaches to health have also been shown to result in positive health outcomes. e581e9f360 In 90 percent of these individuals, the syndrome is caused by the father's Y chromosome's SRY gene being atypically included in the crossing over of genetic information that takes place between the pseudoautosomal regions of the X and Y chromosomes during meiosis in the father. When the X with the SRY gene combines with a normal X from the mother during fertilization, the result is an XX genetic male. Less common are SRY-negative individuals, who appear to be XX genetic females, which is caused by a mutation in an autosomal or X chromosomal gene. Masculinization in those with the condition is variable, and those with the condition are sterile. e581e9f360 When populations share genetic backgrounds and environmental factors, average height is frequently characteristic within the group.
