

Diagram Of A Foot Bones

== See also == f69eb1e602 == Human anatomy == f69eb1e602 Hinge and pivot joints are both types of synovial joint. A hinge joint can be considered a modified sellar/saddle joint, with reduced movement. f69eb1e602 The ligaments are the plantar and two collateral. f69eb1e602 If the big toe and the second toe are the same length (as measured from the MTP joint to the tip, including only the toe bones or phalanges), then the second toe will protrude farther than the big toe, as shown in the photo. If the second toe is shorter... f69eb1e602

Plantar fascia It runs from the tuberosity of the calcaneus (heel bone) forward to the heads of the metatarsal bones (the bone between each toe and the bones of the mid-foot). Recent studies suggest that the plantar fascia is actually an aponeurosis rather than true fascia. The plantar The plantar fascia or plantar aponeurosis is the thick connective tissue aponeurosis which supports the arch on the bottom (plantar side) of the foot. tuberosity of the calcaneus (heel bone) forward to the heads of the metatarsal bones (the bone between each toe and the bones of the mid-foot) f69eb1e602

The short extensor of the toes originates from the forepart of the upper and lateral surface of the calcaneus (in front of the groove for the fibularis brevis tendon), from the interosseous talocalcaneal ligament and the stem of the inferior extensor retinaculum. The fibres pass obliquely forwards and medially across the dorsum of the foot and end in four tendons. The medial part of the muscle, also known as extensor hallucis brevis, ends in a tendon which crosses over the dorsalis pedis artery and inserts into the dorsal surface of the base of the proximal phalanx of the great toe. The other three tendons insert into the lateral sides of the tendons of extensor digitorum longus for the second, third and fourth toes. f69eb1e602 == Movements == f69eb1e602

Extensor digitorum brevis muscle Testut's Anatomy.) Bones of the right foot. Cross-section through middle of leg. Muscles of the front of the leg. Dorsum of foot. Dorsal surface. It helps extend digits 1 through 4. Deep dissection The extensor digitorum brevis muscle (sometimes EDB) is a broad and thin plane of muscular fibers situated on the dorsum of the foot, and dividing at its anterior end into four small tendons f69eb1e602

The direction which the distal bone takes in this motion is rarely in the same plane as that of the axis of the proximal bone; there is usually a certain amount of deviation from the straight line during flexion. f69eb1e602 Posterior tibial tendonitis is a condition that

predominantly affects runners and active individuals. It involves inflammation or tearing of the posterior tibial tendon, which connects the calf muscle to the bones on the inside of the foot. It plays a vital role in supporting the arch and assisting in foot movement. This condition can cause pain, swelling, and potentially lead to flatfoot if left untreated. f69eb1e602 == References == f69eb1e602 The movements permitted in the metatarsophalangeal joints are flexion, extension, abduction, adduction and circumduction. f69eb1e602

Tibial nerve The tibial nerve passes through the popliteal fossa to pass below the arch of soleus. views Diagram of the segmental distribution of the cutaneous nerves of the sole of the foot A schematic of the sacral plexus with the origin of the tibial The tibial nerve is a branch of the sciatic nerve f69eb1e602

The bones of children are very malleable in infancy. This will generally mean that, despite the presence of a coalition, the bones can deform enough to allow painless walking until the child's skeleton has matured enough. 'Skeletal maturing' means that bone is laid down in the tissue that forms the immature bone... f69eb1e602

Morton's toe This condition is the result of a premature closing of the first metatarsal's growth plate, resulting in a short big toe, giving the second toe the appearance of being long compared to the first toe. It is a type of brachymetatarsia. It is a type of brachymetatarsia. This Morton's toe, also known as Greek toe, is the condition of having a first metatarsal bone that is shorter than the second metatarsal (see diagram). toe, is the condition of having a first metatarsal bone that is shorter than the second metatarsal (see diagram) f69eb1e602

Examples of ginglymoid joints are the interphalangeal joints of the hand and those of the foot and the joint between the humerus and ulna. The knee joints and ankle joints are less typical, as they allow a slight degree of rotation or side-to-side movement in certain positions of the limb. The knee is the largest hinge joint in the human body. f69eb1e602

Metatarsophalangeal joints They are analogous to the knuckles of the hand, and are consequently known as toe knuckles in common speech. The region of skin directly below the joints forms the ball of the foot. They are condyloid joints, meaning that an elliptical or rounded surface (of the metatarsal bones) comes close to a shallow cavity (of the proximal phalanges). They are analogous to the knuckles of the hand, and are consequently The metatarsophalangeal joints (MTP joints) are the joints between the metatarsal bones of the foot and the proximal bones (proximal phalanges) of the toes. between the metatarsal bones of the foot and the proximal bones (proximal phalanges) of the toes f69eb1e602

== Structure == f69eb1e602

Tarsal coalition The term 'coalition' means a coming together of two or more entities to merge into one mass (in the case of bones, see synostosis). The term 'coalition' means a coming together Tarsal coalition is an abnormal connecting bridge of tissue between two normally-separate tarsal (foot) bones, and is considered a sort of birth defect. There are other bone coalition combinations possible, but they are very rare and lack published literature. connecting bridge of tissue between two normally-separate tarsal (foot) bones, and is considered a sort of birth defect. This area is called the sinus tarsi. The tissue connecting the bones, often referred to as a "bar", may be composed of fibrous or osseous tissue. Symptoms tend to occur in the same location, regardless of the location of coalition: on the lateral foot, just anterior and below the lateral malleolus. The two most common types of tarsal coalitions are calcaneo-navicular (calcaneonavicular bar) and talo-calcaneal (talocalcaneal bar), comprising 90% of all tarsal coalitions

Quadrant tubercle The metatarsal bones behind the toes are of different lengths, and the relative lengths vary between people. For most feet, a smooth curve can be traced through the joints at the bases of the toes (the metatarsal-phalangeal, or MTP, joints). But in Morton's foot, the line has to bend more sharply to go through the base of the big toe, as shown in the diagram. This is because the first metatarsal, behind the big toe, is short compared to the second metatarsal, next to it. The longer second metatarsal puts the MTP joint at the base of the second toe further forward. == Posterior tibial tendonitis == Anatomy == Structure ==

Tibialis posterior muscle This condition The tibialis posterior muscle is the most central of all the leg muscles, and is located in the deep posterior compartment of the leg. It is the key stabilizing muscle of the lower leg. connects the calf muscle to the bones on the inside of the foot. It plays a vital role in supporting the arch and assisting in foot movement

The tarsus articulates with the bones of the metatarsus, which in turn articulate with the proximal phalanges of the toes. The joint between the tibia and fibula above and the tarsus below is referred to as the ankle joint proper.

Hinge joint According to one classification system they are said to be uniaxial (having one degree of freedom). bone; there is usually a certain amount of deviation from the straight line during flexion. The articular surfaces of the bones are connected by strong A hinge joint (ginglymus or ginglymoid) is a bone joint where the articular surfaces are molded to each other in such a manner as to permit motion only in one plane

The articular surfaces of the bones are connected by strong collateral ligaments. In humans the largest bone in the tarsus is the calcaneus, which is the weight-bearing bone within the heel of the foot.

Tarsus (skeleton) tarsus (pl. : tarsi) is a cluster of seven articulating bones in each foot situated between the lower end of the tibia and the fibula of the lower leg and the metatarsus. It is made up of the midfoot (cuboid, medial, intermediate, and lateral cuneiform, and navicular) and hindfoot (talus and calcaneus). : tarsi) is a cluster of seven articulating bones in each foot situated between the lower end of the tibia and the fibula of the lower leg and the In the human body, the tarsus (pl f69eb1e602
