Sedative Various kinds of sedatives can be distinguished, but the majority of them affect the neurotransmitter gamma-aminobutyric acid (GABA). Most sedatives produce relaxing effects by increasing GABA activity. They are central nervous system (CNS) depressants and interact with brain activity, causing its deceleration. Cyproheptadine (Periactin) Diphenhydramine (Benadryl, DPH) Doxylamine (Unisom) Hydroxyzine (Atarax, Vistaril) Promethazine (Phenergan) Pyrilamine General anaesthetics A sedative, or tranquilizer, is a substance that induces sedation by reducing irritability or excitement e0d9cdd860

Drug injection Hydroxyzine (brand name Atarax, and Vistaril) Drug injection is a method of introducing a drug into the bloodstream via a hollow hypodermic needle, which is pierced through the skin into the body (usually intravenously, but also at an intramuscular or subcutaneous, location). Intravenous therapy, a form of drug injection, is universally practiced in modernized medical care. As of 2004, there were 13. (including the loss of limbs due to vascular injury) or death can occur when it is used in this manner. 2 million people worldwide who self-administered injection drugs outside of medical supervision, of which 22% are from developed countries e0d9cdd860

At the moment the title appears on the screen, a wide rubber band is shown being stretched to the limit until it snaps. The narrator opens with the words, "After the day's work and worries are done, what is more fun for a man than to come home to a quiet house with happy children and a loving spouse?" At that point, two noisy children, a boy and a girl, run into the bedroom where their father is in bed reading a thick book entitled "Relax Relax Relax!". Their mother, the "relaxed wife" of the title, tell them to be quiet. As they leave the girl says "goodnight mother... e0d9cdd860 Common side effects include sleepiness, poor coordination, and an upset stomach. Anxiolytic This effect is in contrast to anxiogenic agents which increase anxiety. it does not disrupt sleep architecture nor does it cause cognitive or psychomotor impairment. Anxiolytic medications are used for the treatment of anxiety disorders and their related psychological and physical symptoms. Hydroxyzine (Atarax) is an antihistamine originally approved An anxiolytic (; also antipanic or anti-anxiety agent) is a medication or other intervention that reduces anxiety e0d9cdd860

Anxiety is a naturally occurring emotion and response. When anxiety levels exceed the tolerability of a person, anxiety disorders may occur. People with anxiety disorders can exhibit fear responses, such as defensive behaviors, high levels of alertness, and negative emotions. Those with anxiety disorders may have concurrent psychological disorders, such as depression. Anxiety disorders are classified using six possible clinical assessments: e0d9cdd860 == Terminology == e0d9cdd860 Although the general public typically uses the word "antihistamine" to describe drugs for treating allergies, physicians and scientists use the term to describe a class of drug that opposes the activity of histamine receptors in the body. In this sense of the word, antihistamines are subclassified according to the histamine receptor that they act upon. The two largest classes of antihistamines are H1-antihistamines and H2-antihistamines. e0d9cdd860

The first benzodiazepine, chlordiazepoxide (Librium), was discovered accidentally by Leo Sternbach in 1955, and was made available in 1960 by Hoffmann-La Roche, which followed up by developing diazepam (Valium) in 1963. Ashton CH. Archived from Benzodiazepines (BZD, BDZ, BZs), colloquially known as "benzos", are a class of central nervous system (CNS) depressant drugs whose core chemical structure is the fusion of a benzene ring and a diazepine ring. The introduction of selective serotonin reuptake inhibitors (SSRIs), among other factors, decreased rates of BZD prescription, but they remain frequently used worldwide. By 1977, benzodiazepines were the most prescribed medications globally e0d9cdd860

== Plot == e0d9cdd860 This group is related to hypnotics. The term sedative describes drugs that serve to calm or relieve anxiety, whereas the term hypnotic describes drugs whose main purpose is to initiate, sustain, or lengthen sleep. Because these two functions frequently overlap, and because drugs in this class generally produce dose-dependent effects (ranging from anxiolysis to loss of consciousness), they are often referred to collectively as sedative-hypnotic drugs. e0d9cdd860 Insomnia can occur independently or as a result of another problem. Conditions that can result in insomnia include psychological stress, chronic pain, heart failure, hyperthyroidism, heartburn, restless leg syndrome, perimenopause, menopause, certain

medications, and use of drugs such as caffeine, nicotine, and alcohol. Risk factors include working night shifts and sleep apnea. Diagnosis is based on sleep habits and an examination to look for underlying causes. A sleep study may be done to look for underlying sleep disorders. Screening may be done with questions like "Do you experience difficulty sleeping?" or "Do you have difficulty falling or staying asleep?" e0d9cdd860

Hypnotic diphenhydramine, hydroxyzine, and promethazine and the antidepressants amitriptyline and mirtazapine among others, were not included in analyses due to insufficient A hypnotic (from Greek Hypnos, sleep), also known as a somnifacient or soporific, and commonly known as sleeping pills, are a class of psychoactive drugs whose primary function is to induce sleep and to treat insomnia (sleeplessness). Certain hypnotics can be used to treat non-restorative sleep and associated symptoms in conditions like fibromyalgia as well. Some hypnotics are also used to treat narcolepsy and hypersomnia by improving sleep at night and thereby reducing daytime sleepiness e0d9cdd860

Common side effects include sleepiness, depression, suppressed emotions, mild to severe decreases in motor skills, hiccups, dulling or declining of cognition, decreased alertness, dry mouth (mildly), decreased heart rate, impairment of judgment (usually in higher than therapeutic doses), and decreased memory formation, depending on dosage. Some of the sedation and drowsiness may improve within a few days. e0d9cdd860 Alprazolam was developed by Jackson Hester Jr. at the Upjohn Company and patented in 1971 and approved for medical use in the United States in 1981. Benzodiazepines are depressants that enhance the effect of the neurotransmitter gamma-aminobutyric acid (GABA) at the GABAA receptor, resulting in sedative, hypnotic (sleep-inducing), anxiolytic (anti-anxiety), anticonvulsant, and muscle relaxant properties. Diphenhydramine Diphenhydramine is also a potent anticholinergic. It is also less commonly used for tremors in parkinsonism, and nausea. it blocks histamine) with sedative effects. e. It is mainly used to treat allergies, insomnia, and symptoms of the common cold. This may manifest as agitation, anxiety, or restlessness rather than sedation. Although generally considered sedating, diphenhydramine can cause paradoxical central nervous system stimulation in some individuals, particularly at higher doses. It is taken by mouth, injected into a vein, injected into a muscle, or applied to the skin. It is a first-generation H1-antihistamine (i. On the other hand, hydroxyzine, a first-generation antihistamine that lacks significant anticholinergic effects, may be used to treat anxiety, although Diphenhydramine, or Diphenylhydramine, sold under the brand name Benadryl among others, is an antihistamine and sedative. Ketamine administered intravenously in clinical settings has become more common. Although there are various methods of taking drugs, injection is favoured by some people as the full effects of the drug are experienced very quickly, typically in five to ten seconds. Insomnia all. Sleep quality and Insomnia, also known as sleeplessness, is a sleep disorder causing difficulty falling asleep or staying asleep for as long as desired. Insomnia can be short-term, lasting for days or weeks, or long-term, lasting more than a month. The concept of the word insomnia has two distinct possibilities: insomnia disorder or insomnia symptoms. It may result in an increased risk of accidents as well as problems focusing and learning. Insomnia is typically followed by daytime sleepiness, low energy, irritability, and a depressed mood. They incorrectly believe it takes them an abnormally long time to fall asleep, and they underestimate how long they stay asleep e0d9cdd860
