Ronald Fisher For his contributions to biology, Richard Dawkins declared Fisher to be the greatest of Darwin's successors. He has been described as "a genius who almost single-handedly created the foundations for modern statistical science" and "the single most important figure in 20th century statistics". Leek, Fisher is the most influential scientist of all time on the basis of the number of citations of his contributions. He is also considered one of the founding fathers of Neo-Darwinism. this book Fisher also outlined the lady tasting tea, now a famous design of a statistical randomized experiment which uses Fisher's exact test and is the Sir Ronald Aylmer Fisher (17 February 1890 – 29 July 1962) was an English polymath who was active as a mathematician, statistician, biologist, geneticist, and

academic. According to statistician Jeffrey T. In genetics, Fisher was the one to most comprehensively combine the ideas of Gregor Mendel and Charles Darwin, as his work used mathematics to combine Mendelian genetics and natural selection; this contributed to the revival of Darwinism in the early 20th-century revision of the theory of evolution known as the modern synthesis

commonly applied when the test statistic would follow a normal distribution if the value of a scaling term in the test statistic were known (typically, the scaling term is unknown and is therefore a nuisance parameter). The t-test's most common application is to test whether the means of two populations are significantly different. In many cases, a Z-test will yield very similar results to a t-test because the latter converges to the former as the size of the dataset increases. It is any statistical hypothesis test in which the test statistic follows a Student's t-distribution under the null hypothesis

Assumptions, parametric and non-parametric: There are

Test De Fisher Exact

two groups of statistical tests, parametric and non-parametric. The choice between these two groups needs to be justified.

Parametric tests assume that the data follow a particular distribution, typically a normal distribution, while non-parametric tests make no assumptions about the distribution. Non-parametric tests have the advantage of being more resistant to misbehaviour of the data, such as outliers. They also have the disadvantage of being less certain in the statistical estimate.
